

CLINICAL RESULTS OF LIPOSUCTION WITH ULTRASONIC CAVITATION EQUIPMENT

The sample consisted of 27 visits by patients, T-tests. We could not apply Wilcoxon or, for example, linear analogue scale. Preliminary results were promising and encouraging in terms of the treatment method, but due to the small number of cases, the research does not meet scientific criteria as of yet.

There was no factual background available for reference points. These were defined using anatomical details and based on our own know-how and reliable medical articles. We used an accurate and standardized method with focus on technical expertise.

Studied points that we can consider reliable are 4 cm, 10 cm, hypogastrium and both sides at the thickest points.

Results: 1st treatment - decrease in subcutaneous fat 25% +- 15%
2nd treatment - 10%+-12%, and 3rd treatment 5-6%+-12%.

I find these results very encouraging but it continues to be important to carry out further studies.

We are definitely heading in the right direction with ultrasound-assisted liposuction when considering the comfort of the patient.
